1.1 2011-

2019 AMC 12A/7

November 28, 2024

Melanie computes the mean μ, the median M, and the modes of the 365 values that are the dates in the months of 2019. Thus her data consist of 12 1s, 12 2s, . . . , 12 28s, 11 29s, 11 30s, and 7 31s. Let d be the median of the modes. Which of the following statements is true?

(A) $\mu < d < M$ **(B)** $M < d < \mu$ **(C)** $d = M = \mu$ **(D)** $d < M < \mu$ **(E)** $d < \mu < M$

Solution:

I first find the mode of the numbers. The mode will be all the numbers from 1 to 28 since every month has those. Therefore, the median of this will be 14.5.

The median of all the numbers will be in the 183rd spot of all the data. There will be 12 of each number from 1 to 28, and since $12(15) = 180$, we can assume that the 183rd spot will have a 16 there.

For the mean, if we assume that each month as 31 days, then the mean of all these values will be 16. However, since we counted more days than actually in the year, we assume that the mean is less than 16.

Therefore the answer is $\boxed{\textbf{E}}$.

2019 AMC 12B/7

November 26, 2024

What is the sum of all real numbers x for which the median of the numbers $4, 6, 8, 17,$ and x is equal to the mean of those five numbers?

Solution:

Ok the mean of this is simple to calculate, it is just $\frac{4+6+8+17+x}{x} = \frac{35+x}{5}$.

There are three possible medians, they are 6, 8, and x.

Case 1: median is 6.

This only works when $x \leq 6$, so for this to work, we need $\frac{35+x}{5} = 6$. This is possible when $x = -5$.

Case 2: median is 8.

This only works when $x \geq 8$, so for this to work, we need $\frac{35+x}{5} = 8$. The only value of x that this works for is $x = 5$, so this is not a solution.

Case 3: median is x.

This case is only for $6 < x < 8$. We need for $\frac{35+x}{5} = x$. Simplifying this, we get $x = \frac{35}{4}$. This value is not less than 8, so we banish this to the shadow realm!! Ok the answer is $\boxed{-5}$ btw.

2018 AMC 12B/2

November 28, 2024

Sam drove 96 miles in 90 minutes. His average speed during the first 30 minutes was 60 mph (miles per hour), and his average speed during the second 30 minutes was 65 mph. What was his average speed, in mph, during the last 30 minutes?

Solution:

Using $d = rt$ we can find that in the first 30 minutes, Sam drove $60 \cdot 0.5 = 30$ miles.

In the next 30 minutes, Sam drove $65 \cdot 0.5 = 32.5$ miles.

Therefore in the last 30 minutes, he drove $96 - 32.5 - 30 = 33.5$ miles. Since this is the rate for 30 minutes, simply multiply this value by two using the power of dimensional analysis in chemistry to get $\boxed{67}$ mph.

2017 AMC 12B/21

November 27, 2024

Last year Isabella took 7 math tests and received 7 different scores, each an integer between 91 and 100, inclusive. After each test she noticed that the average of her test scores was an integer. Her score on the seventh test was 95. What was her score on the sixth test?

(A) 92 **(B)** 94 **(C)** 96 **(D)** 98 **(E)** 100

Solution:

The smallest possible sum and the largest possible sum that is divisible by 7 just happens to be the lowest 7 and highest 7 numbers added together.

For example the highest possible sum is just $100 + 99 + 98 + 97 + 96 + 95 + 94 = 679 = 7(97)$, and the lowest possible sum is $91 + 92 + 93 + 94 + 95 + 96 + 97 = 658 = 7(94)$. Therefore, the only two other sums that can be $7(95)$ and $7(96)$, or 665 and 672.

Now we can subtract 95 from all of them to find the sum of the first 6 test scores.

After we subtract 95 from all the numbers, we get $563, 570, 577, 584$. The only one of these divisible by 6 is 570, so we know that this is the sum of the first six test scores.

The sum of the first five test scores will have to be divisible by 5, so note that because of this, the only numbers you can subtract from 570 that will result in a number that can be divisible by 5 are 95 and 100. 95 cannot be subtracted from this because note the condition in the question that states that each score has to be different, so the answer is $\boxed{100}$.

2014 AMC 12A/19

December 5, 2024

There are exactly N distinct rational numbers k such that $|k| < 200$ and

$$5x^2 + kx + 12 = 0$$

has at least one integer solution for x. What is N?

Solution:

First, rearrange the equation as $5x^2 + kx = -12$. Factoring out x we get $x(5x + k) = -12$. Solving for k we get $\frac{-12}{x} - 5x$.

From here we can see that when x is a positive value, and then k will be negative. So, we can see that $|-5x| < 200$, since the same will be for negative values of x.

Solving this inequality yields $-200 < -5x < 200$ or $40 > x > -40$, where $x \neq 0$. So we can see that the values from 1 to 39 and -39 to -1 will be the only values that work.

Therefore $39 + 39 = \boxed{78}$.

Note that the value 0 will not work because the $\frac{-12}{x}$ is undefined.

2013 AMC 12A/16

November 21, 2024

A, B, C are three piles of rocks. The mean weight of the rocks in A is 40 pounds, the mean weight of the rocks in B is 50 pounds, the mean weight of the rocks in the combined piles A and B is 43 pounds, and the mean weight of the rocks in the combined piles A and C is 44 pounds. What is the greatest possible integer value for the mean in pounds of the rocks in the combined piles B and C?

(A) 55 **(B)** 56 **(C)** 57 **(D)** 58 **(E)** 59

Solution:

We can write a few equations from the information given:

$$\frac{A}{a} = 40 \qquad \frac{B}{b} = 50 \qquad \frac{A+B}{a+b} = 43 \qquad \frac{A+C}{a+c} \qquad \frac{B+C}{b+c} = x$$

where a, b, c are the number of rocks in piles A, B, C respectively.

$A = 40b$ and $B = 50b$ as a result.

We can solve for a in terms of b now:

$A + B = 43(a + b) = 43a + 43b$.

Substituting $A + B = 40b + 50b$, we get $40a + 50b = 43a + 43b$.

Solving for a, we get $7b = 3a$, and $a = \frac{7}{3}b$.

We can also solve for C.

$$\begin{aligned} A + C &= 44a + 44c \\ 40a + C &= 44a + 44c \\ C &= 44c + 4a \end{aligned}$$

Also, we can write C in terms of b as well:

$$\begin{aligned} B + C &= x(b + c) \\ 50b + C &= x(b + c) \\ C &= xc + b(x - 50) \end{aligned}$$

Putting these equations equal to each other:

$$\begin{aligned} 44c + 4a &= xc + b(x - 50) \\ (44 - x)c + 4\left(\frac{7}{3}\right)b &= (x - 50)b \\ (44 - x)c + \frac{28}{3}b &= (x - 50)b \\ (44 - x)c &= \left(x - 50 - \frac{28}{3}\right)b \\ c &= \frac{\left(x - 50 - \frac{28}{3}\right)b}{44 - x} \end{aligned}$$

Now we can see from the answer choices that the denominator will be negative, which therefore means we need the numerator to be negative as well to result in a positive value for c.

$50 + \frac{28}{3}$ is equal to $59\frac{1}{3}$, so the largest value x that can result in the equation resulting in a positive number is $\boxed{59}$.

2011 AMC 12A/18

December 1, 2024

Suppose that $|x+y|+|x-y|=2$. What is the maximum possible value of x^2-6x+y^2?

Solution:

There are four cases:

$(x+y)+(x-y)$ yields $x=1$.

$-(x+y)+(x-y)$ yields $y=-1$.

$(x+y)-(x-y)$ yields $y=1$.

$-(x+y)-(x-y)$ yields $x=-1$.

This expression is maximized when the $-6x$ term is positive, and x^2 and y^2 are always going to be 1 each, so it is maximized at $(-1,\pm 1)$, or $1^2-6(-1)+1^2=\boxed{8}$.

1.2 2000-2010

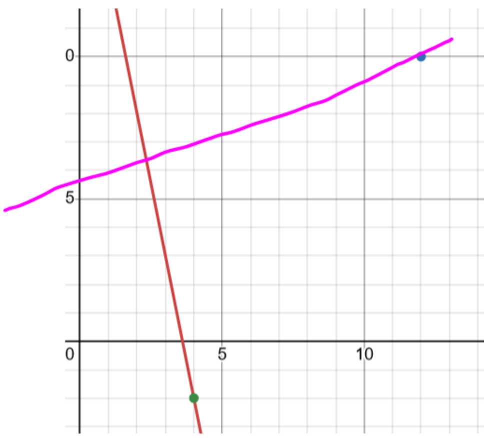
2007 AMC 12A/13

December 6, 2024

A piece of cheese is located at $(12,10)$ in a coordinate plane. A mouse is at $(4,-2)$ and is running up the line $y=-5x+18$. At the point (a,b) the mouse starts getting farther from the cheese rather than closer to it. What is $a+b$?

Solution:

First we should graph the line $y=-5x+18$ and label the points.



The mouse will be closest to the cheese when it is at the foot of the perpendicular line from $(12,10)$, so we need to find the perpendicular line of $y=-5x+18$ that includes the point $(12,10)$.

From the point-slope formula we have

$$y-10=\frac{1}{5}(x-12)$$

Putting this in a system with the other equation, we have

$$\begin{aligned} y-10&=\frac{1}{5}x-\frac{12}{5} \\ y&=-5x+18 \end{aligned}$$

When we put both of these equations equal to y and equal them to each other, we have

$$\begin{aligned}-5x+18 &= \frac{1}{5}x+\frac{38}{5}\\ -25x+90 &= x+38\\ -26x &= -52\\ x &= 2\end{aligned}$$

Plugging this back into $y=-5x+18$, we get $y=8$.

The point at which the mouse is closest to the cheese is at $(2,8)$, so $2+8=\boxed{10}$.

2006 AMC 12A/11

December 5, 2024

Which of the following describes the graph of the equation $(x+y)^2=x^2+y^2$?

(A) the empty set (B) one point (C) two lines (D) a circle (E) the entire plane

Solution:

Simplifying the equation we have:

$$\begin{aligned}(x+y)^2 &= x^2+y^2\\ x^2+y^2+2xy &= x^2+y^2\\ 2xy &= 0\end{aligned}$$

From this we can see that $x=0$ or $y=0$, so the graphs will just be the x-axis and the y-axis which is $\boxed{\text{two lines}}$.

2005 AMC 12B/7

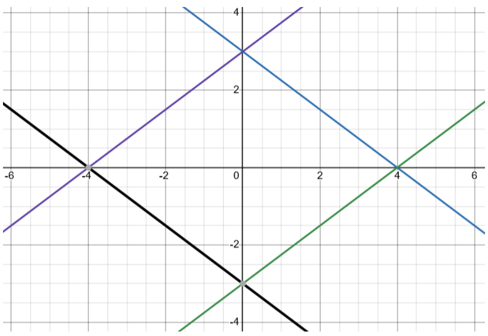
December 4, 2024

What is the area enclosed by the graph of $|3x|+|4y|=12$?

Solution:

The graph produced will be a rhombus bounded by 4 lines:

$3x+4y=12$ $3x-4y=12$ $-3x+4y=12$ $-3x-4y=12$



Now the area of a rhombus is $\frac{1}{2}$ the product of the diagonals. So, $\frac{1}{2}\cdot 6\cdot 8=\boxed{24}$.

2004 AMC 10A/4

November 30, 2024

What is the value of x if $|x-1| = |x-2|$?

Solution:

Case 1: The absolute values are less than or greater than zero.

This case does not work since $x-1 \neq x-2$.

Case 2: One is positive, one is negative.

Therefore, we have $1-x = x-2$. Solving we get $x = \boxed{\dfrac{3}{2}}$.

2000 AMC 12/5

December 2, 2024

If $|x-2| = p$, where $x < 2$, then $x - p =$

Solution:

Ok so $x < 2$ so that means $x-2$ is negative, so $-(x-2) = p$, or $-x+2 = p$, so $x = 2-p$.

Therefore $x - p = 2 - p - p = \boxed{2-2p}$.

2000 AMC 12/14

November 28, 2024

When the mean, median, and mode of the list

$$10, 2, 5, 2, 4, 2, x$$

are arranged in increasing order, they form a non-constant arithmetic progression. What is the sum of all possible real values of x?

Solution:

The list can be written as $2, 2, 2, 4, 5, 10$ with x somewhere.

The mode of this list is 2 regardless of anything.

The mean of this list is $\frac{2+2+2+4+5+10+x}{7} = \frac{25+x}{7}$.

The medians can be 2, 4, or x.

If the median is 2 and the mode is 2, the mean has to be 2, this is kinda erm constant.

If the median is 4 we have $\frac{25+x}{7}$ equal to either 0, 3, or 6 as the only ways to make this an arithmetic sequence.

$\frac{25+x}{7} = 0$ results in a negative number, putting this as x will make the median no longer equal 4 so it is a bad number. The same applies for $\frac{25+x}{7} = 3$. However $\frac{25+x}{7} = 6$ results in a number greater than 4, and so $x = 17$.

Now the last case is when x is the median. In this case, there is an arithmetic sequence of $2, x, \frac{25+x}{7}$ because the median is x which is greater than 2 and the mean of the numbers will be greater than the median.

The differences between each term have to be the same, so

$$\begin{aligned} x-2 &= \frac{25+x}{7} - x \\ 2x &= \frac{25+x}{7} + \frac{14}{7} \\ 2x &= \frac{39+x}{7} \\ 14x &= 39+x \\ 13x &= 39 \\ x &= 3 \end{aligned}$$

Since this number for x is a valid median $x=3$ is also a solution.

Therefore $17+3=\boxed{20}$.

2000 AMC 12/20

November 24, 2024

If $x, y,$ and z are positive numbers satisfying

$$x+\frac{1}{y}=4, \qquad y+\frac{1}{z}=1, \qquad \text{and} \qquad z+\frac{1}{x}=\frac{7}{3}$$

Then what is the value of xyz ?

Solution:

I noticed first that we can get xyz by multiplying the equations together.

$$\begin{gathered} \left(x+\frac{1}{y}\right)\left(y+\frac{1}{z}\right)=4 \\ \left(xy+\frac{x}{z}+1+\frac{1}{yz}\right)\left(z+\frac{1}{x}\right)=\frac{28}{3} \\ xyz+y+x+\frac{1}{z}+z+\frac{1}{x}+\frac{1}{y}+\frac{1}{xyz}=\frac{28}{3} \end{gathered}$$

Substituting values in, we get

$$\begin{gathered} xyz+\frac{1}{xyz}+4+1+\frac{7}{3}=\frac{28}{3} \\ xyz+\frac{1}{xyz}=\frac{28}{3}-\frac{22}{3}=2 \end{gathered}$$

We can see that $\boxed{xyz=1}$ is a solution to this.

1.3 Before 2000

1987 AHSME/15

November 24, 2024

If (x, y) is a solution to the system

$$xy=6 \qquad \text{and} \qquad x^2y+xy^2+x+y=63,$$

find x^2+y^2.

Solution:

Factoring the second equation, we get $xy(x+y)+x+y=63$.

Substituting in xy, we get $6(x+y)+x+y=6x+6y+x+y=7x+7y=63$ or $x+y=9$.

Squaring both sides, we get $(x+y)^2=x^2+y^2+2xy=81$. Substituting in xy once again, we get $x^2+y^2+2(6)=81$, so $x^2+y^2=81-12=69$.

1951 AHSME/50

November 29, 2024 Tom, Dick and Harry started out on a 100-mile journey. Tom and Harry went by automobile at the rate of 25 mph, while Dick walked at the rate of 5 mph. After a certain distance, Harry got off and walked on at 5 mph, while Tom went back for Dick and got him to the destination at the same time that Harry arrived. The number of hours required for the trip was:

Solution:

Let x be the amount of miles that Harry travels on the car and y be the amount that Tom backtracks to get Dick (old ah names I think).

Tom's equation will be $\frac{x}{25}+\frac{y}{25}+\left(\frac{100}{25}-\frac{x-y}{25}\right)$

Dick's equation will be $\frac{x}{5}-\frac{y}{5}+\left(\frac{100}{25}-\frac{x-y}{25}\right)$

Harry's equation will (not be so hairy) $\frac{x}{25}+\left(\frac{100}{5}-\frac{x}{5}\right)$

Note that Tom and Dick's last terms in parenthesis are the same because they will be traveling the same distance at this point in time.

Since all these equations give the time that it takes for each of these members to get to the destination, we can set them all equal to each other :-D

Aight so

$$\frac{x+y+100-x+y}{25}=\frac{5x-5y+100-x+y}{25}=\frac{x+500-5x}{25}$$
$$2y+100=4x-4y+100=500-4x$$

We can solve for y in terms of x now:

We have $2y+100=4x-4y+100$, so cancelling out the 100 and adding the respective terms to both sides, we get $6y=4x$ or $y=\frac{2}{3}x$.

Now substituting this value for y back in to the $2y+100=500-4x$, we get that $\frac{4}{3}x+100=500-4x$. So after doing some calculations (i hate calculations), we get $x=75$.

Plugging this value for x back into $y=\frac{2}{3}x$, we get $y=50$.

Now since we have both values of x and y, we can now plug it back to one of the original equations we defined. Since Harry's little equation looks the last harriest, I plug it back into this.

$\frac{75}{25}+\frac{100-75}{5}=3+5=\boxed{8}$

---

2 AIME

2.1 2011-2020

2016 AIME I/1

December 4, 2024

For $-1 < r < 1$, let $S(r)$ denote the sum of the geometric series

$$12 + 12r + 12r^2 + 12r^3 + \cdots .$$

Let a between -1 and 1 satisfy $S(a)S(-a) = 2016$. Find $S(a) + S(-a)$.

Solution:

We can see that $S(a) = 12 + 12a + 12a^2 + 12a^3 + \cdots = \frac{12}{1-a}$.

We can also see that $S(-a) = 12 + 12(-a) + 12(-a)^2 + 12(-a)^3 + \cdots = \frac{12}{1+a}$.

So, $\frac{12}{1-a} \cdot \frac{12}{1+a} = \frac{144}{(1-a)(1+a)} = 2016$.

Now note that we are looking for $S(a) + S(-a) = \frac{12}{1-a} + \frac{12}{1+a}$. Simplifying this, we get $\frac{12(1+a)+12(1-a)}{(1-a)(1+a)} = \frac{24}{(1-a)(1+a)}$.

This looks similar to the equation above that equals 2016, and we can see all we have to do is divide the equation by 6, so $\frac{\frac{144}{(1-a)(1+a)}}{6} = \frac{2016}{6} = \boxed{336}$.

2015 AIME II/14

November 18, 2024

Let x and y be real numbers satisfying $x^4y^5 + y^4x^5 = 810$ and $x^3y^6 + y^3x^6 = 945$. Evaluate $2x^3 + (xy)^3 + 2y^3$.

Solution:

We let $a = xy$ and $b = x + y$.

Factoring $x^4y^4 + y^4x^5 = 810$ we get $(xy)^4(x + y) = 810$ and substituting we get $(a^4)(b) = 810$.

Factoring the other takes a little more steps.

When we factor $x^3y^6 + y^3x^6$ we get $(xy)^3 + (x^3 + y^3)$.

Note that $(x + y)^3 = x^3 + y^3 + 3xy(x + y) \implies b^3 = x^3 + y^3 + 3ab$, so $x^3 + y^3 = b^3 - 3ab$.

Therefore, factoring $x^3y^6 + y^3x^6 = 945$ gets $(a^3)(b^3 - 3ab) = 945$.

Note we are also looking for the value of $2(x^3 + y^3) + (xy)^3$ or $2(b^3 - 3ab) + a^3$ or $2b(b^2 - 3a) + a^3$.

Dividing the two factored equations we get:

$$\begin{aligned}\frac{(a^3)(b^3-3ab)}{(a^4)(b)} &= \frac{945}{810}\\ \frac{a^3b^3-3a^4b}{a^4b} &= \frac{945}{810}\\ \frac{b^2}{a}-3 &= \frac{945}{810}\\ \frac{b^2}{a}-3 &= \frac{7}{6}\\ \frac{b^2}{a} &= \frac{25}{6}\end{aligned}$$

Now for some manipulations.

Solving for a we get $a = \frac{6}{25}b^2$.

I didn't know a better way to go from here, so I plugged it into the equation defined earlier, $(a^4)(b) = 810$ to get $\left(\frac{6}{25}b^2\right)^4(b) = 810$.

After cheating with some desmos calculations this resulted in $\frac{1296}{390625}b^9 = 810$.

Solving for b we get $b^9 = \frac{890\cdot 390625}{1296}$

Using some more online calculators for simplifying fractions, I got $b^9 = \frac{1953125}{8}$. Now the cube root of 1953125. Now 1953125 looked like some power of 5 so I assumed it was 5^9 and desmos said it was correct! Happy Stasya!

So $b^3 = \sqrt[3]{\frac{1953125}{8}} = \frac{125}{2}$.

Now from earlier, there was the equation $a = \frac{6}{25}b^2$. We are looking for a^3 (we will look for $2b(b^2-3a)$ momentarily).

So we can take what we know and plug it into a^3:

$$\begin{aligned}a^3 &= \left(\frac{6}{25}b^2\right)^3\\ &= \frac{6^3}{25^3}b^6\\ &= \frac{6^3}{25^3}b^3b^3\\ &= \frac{6^3}{25^3}\frac{125}{2}\frac{125}{2} = \frac{6^3}{4} = 54\end{aligned}$$

We have found that $a^3 = 54$!

Ok now we need to find out $2b(b^2-3a)$ to finish the problem.

We can rewrite this as $2b^3 - 6ab$ to make this easier actually since we already know b^3.

We know that $a^3 = 54$, so we can plug that into one of the first equations we defined at the top, $(a^4)(b) = 810$.

This results in $54ab = 810$, so $ab = \frac{810}{54} = 15$.

Now we only need to plug these values in: $2\left(\frac{125}{2}\right) - 6(15) = 125 - 90 = 35$.

Adding $a^3 = 54$ with what I just found, we get $54 + 35 = \boxed{89}$.

2012 AIME I/2

December 6, 2024

The terms of an arithmetic sequence add to 715. The first term of the sequence is increased by 1, the second term is increased by 3, the third term is increased by 5, and in general, the kth term is increased by the kth odd positive integer. The terms of the new sequence add to 836. Find the sum of the first, last, and middle terms of the original sequence.

Solution:

Let the arithmetic sequence be $a_1 + a_2 + a_3 + \cdots + a_n = 715$.

We also have $(a_1 + 1) + (a_2 + 3) + (a_3 + 5) + (a_n + (2n - 1)) = 836$.

Notice that the first arithmetic sequence is in the second arithmetic sequence. We can rewrite the second arithmetic sequence as

$$(a_1 + a_2 + a_3 + \cdots + a_n) + (1 + 3 + 5 + \cdots + (2n - 1))$$

Which is also $715 + (1 + 3 + 5 + \cdots + (2n - 1)) = 836$.

Note that the sum $(1 + 3 + 5 + \cdots + (2n - 1)) = n^2$. Therefore we have $n^2 = 836 - 715 = 121$. We now have $n = 11$.

Now we are looking for the sum of $a_1 + a_6 + a_{11}$. We know that a_6 will be the average of a_1 and a_{11}, so from that we know that $a_1 + a_{11} = 2a_6$.

Now if we continue the average of a_2 and a_{10} will also be a_6 so the sum of a_2 and a_{10} is $2a_6$.

If we continue this, we should see that the sum of $a_1 + a_2 + a_3 + \cdots + a_{11} = 735$ will just be equivalent to $11a_6 = 735$.

Note that $a_1 + a_{11} + a_6 = 2a_6 + a_6 = 3a_6$, so we can just multiply 735 by $11a_6 = 735$ by $\frac{3}{11}$ to get $3a_6 = 715\left(\frac{3}{11}\right) = \boxed{195}$.

2010 AIME I/9

November 25, 2024

Let (a, b, c) be a real solution of the system of equations $x^3 - xyz = 2$, $y^3 - xyz = 6$, $z^3 - xyz = 20$. The greatest possible value of $a^3 + b^3 + c^3$ can be written in the form $\frac{m}{n}$, where m and n are relatively prime positive integers. Find $m + n$.

Solution:

Ok pretty much let $a = x$, $b = y$, and $c = z$.

Then we have

$$a^3 = 2 + abc \qquad b^3 = 6 + abc \qquad c^3 = 20 + abc$$

Also adding these we have $a^3 + b^3 + c^3 = 28 + 3(abc)$.

So we can like substitute $r = abc$ and then multiply the first rewritten equations above so:

$$a^3 = 2 + r$$
$$b^3 = 6 + r$$
$$c^3 = 20 + r$$

Multiplying these, we get $(abc)^3 = r^3 = (2 + r)(6 + r)(20 + r)$.

Ok now we can just expand:

$$\begin{aligned}
r^3 &= (12 + 2r + 6r + r^2)(20 + r) \\
r^3 &= 240 + 12r + 160r + 8r^2 + 20r^2 + r^3 \\
0 &= 240 + 12r + 160r + 8r^2 + 20r^2 \\
0 &= 28r^2 + 172r + 240 \\
0 &= 7r^2 + 43r + 60
\end{aligned}$$

The factors that multiply to 420 that add up to 43 are 28 and 15, so this can be factored to $(7r+15)(r+4)$.

Therefore, $r = -\frac{15}{7}$ and $r = -4$.

Above, we see that $a^3 + b^3 + c^3 = 28 + 3r$, so since both values of r are negative, the negative number closer to 0 will maximize the value.

Therefore, $r = -\frac{15}{7}$.

Plugging this in, we get $a^3 + b^3 + c^3 = 28 + 3\left(-\frac{15}{7}\right)$.

Expanding this, we get $\frac{151}{7}$, so $151 + 7 = \boxed{158}$.

A 100 foot long moving walkway moves at a constant rate of 6 feet per second. Al steps onto the start of the walkway and stands. Bob steps onto the start of the walkway two seconds later and strolls forward along the walkway at a constant rate of 4 feet per second. Two seconds after that, Cy reaches the start of the walkway and walks briskly forward beside the walkway at a constant rate of 8 feet per second. At a certain time, one of these three persons is exactly halfway between the other two. At that time, find the distance in feet between the start of the walkway and the middle person.

Solution:

Ah well Al ends up going 6 ft/sec, Cy goes 8 ft/sec and Bob ends up going 10 ft/sec.

So like pretty early on, we can find that Al will end up somewhere in between Cy and Bob, eventually Al will fall behind, but at earlier times it can be assumed that Al will end up halfway between Cy and Bob.

Therefore we have $\frac{8(t-4)+10(t-2)}{2} = 6t$.

Solving for t we get $8t - 32 + 10t - 20 = 12t$ and $6t = 52$, so $t = \frac{52}{6} = \frac{26}{3}$.

Substituting this into $6t$ for Al, we get $6\left(\frac{26}{3}\right) = \boxed{52}$.

In convex hexagon $ABCDEF$, all six sides are congruent, $\angle A$ and $\angle D$ are right angles, and $\angle B, \angle C, \angle E$, and $\angle F$ are congruent. The area of the hexagonal region is $2116(\sqrt{2}+1)$. Find AB.

Solution:

When we draw the diagram, we get a 45-45-90 triangle with a rectangle and a 45-45-90 triangle again on the top of the rectangle.

From this, we can find the area of the rectangle - so the area of the rectangle is $x(x\sqrt{2})$. The two 45-45-90 triangles create a square, so the area is x^2 so the area of convex hexagon is $x(x\sqrt{2}) + x^2$.

Simplifying, we get $x^2(\sqrt{2}+1)$. From the given statement in the question, we can find that $x^2 = 2116$, so $x = \boxed{46}$.

Find the sum of the roots, real and non-real, of the equation $x^{2001} + \left(\frac{1}{2} - x\right)^{2001} = 0$, given that there are no multiple roots.

Solution:

Let $a = x - \frac{1}{4}$.

Then we have

$$\left(\frac{1}{4} + a\right)^{2001} + \left(\frac{1}{4} - a\right)^{2001} = 0$$

The binomial theorem states that $(a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^{n-k} b^k$

Expanding both terms we get

$$\left(\frac{1}{4} + a\right)^{2001} = \sum_{k=0}^{2001} \binom{2001}{k} \left(\frac{1}{4}\right)^{2001-k} a^k$$

and

$$\left(\frac{1}{4} - a\right)^{2001} = \sum_{k=0}^{2001} \binom{2001}{k} \left(\frac{1}{4}\right)^{2001-k} (-a)^k$$

Adding these two together, we get

$$\sum_{k=0}^{2001} \binom{2001}{k} \left(\frac{1}{4}\right)^{2001-k} (a^k + (-a)^k)$$

Note that $a^k + (-a)^k$ will be equal to zero when k is an odd number, so only when k is an even number will there be a non-zero value and that it will result in $2a^k$ given an even k.

We therefore get:

$$2\sum_{k=0}^{2001} \binom{2001}{k} \left(\frac{1}{4}\right)^{2001-k} a^k = 0$$

Therefore the second term will have an odd power, and therefore a coefficient of 0. Therefore by Vieta's, the sum of the roots will be 0 divided by something, or 0.

Because the highest power will be 2000, then there are 2000 roots. Substituting back to the original equation, we can see that $a = x - \frac{1}{4}$. The sum of the roots of x will be the sum of the roots of $a + 2000 \cdot \frac{1}{4}$ or $\boxed{500}$.

Find $x^2 + y^2$ if x and y are positive integers such that

$$xy + x + y = 71,$$
$$x^2y + xy^2 = 880.$$

Solution:

Let $a = xy$ and $b = x + y$.

By substituting these variables in, we get $a + b = 71$ and $ab = 880$.

We can solve for a by rearranging $a + b = 71$ to $b = 71 - a$.

Substituting this into the second equation, we get $a(71 - a) = 880$.

This simplifies to $a^2 - 71a - 880$.

Factoring this, we get $(a - 16)(a - 55)$, so $a = 16, 55$.

We can show that $a \neq 16$ because in this case, it would mean that $x + y = 55$, and there are no two factors that add up to 55 and can multiply to 16.

So, $a = 55$ or $xy = 55$, so (x, y) is $(11, 5)$ or $(5, 11)$.

Therefore, $5^2 + 11^2 = \boxed{146}$.

Determine all real values of A for which there exist distinct complex numbers x_1, x_2 such that the following three equations hold:

$$\begin{aligned} x_1(x_1+1) &= A \\ x_2(x_2+1) &= A \\ x_1^4+3x_1^3+5x_1 &= x_2^4+3x_2^3+5x_2. \end{aligned}$$

Solution:

Ok I'm going to let $a = x_1$ and $b = x_2$ for this, because for the life of me I can't type underscores.

So we can rewrite the given equations as

$$\begin{aligned} a^2+a &= A \\ b^2+b &= A \\ a^4+3a^3+5a-b^4-3b^3-5b &= 0 \end{aligned}$$

Note that for the third equation I just subtracted stuff.

So let's go factor that third equation

$$\begin{aligned} a^4-b^2+3a^3-3b^3+5a-5b \\ (a^2+b^2)(a^2-b^2)+3(a^3-b^3)+5(a-b) \\ (a^2+b^2)(a+b)(a-b)+3(a-b)(a^2+ab+b^2)+5(a-b)=0 \end{aligned}$$

Note that we can factor out $(a-b)$ from this, therefore we can get

$$(a^2+b^2)(a+b)+3(a^2+ab+b^2)+5=0$$

Now we can find out what $a+b$ is.

We can make $a^2+a=b^2+b$, so we can get a^2-b^2+a-b or $(a+b)(a-b)+(a-b)=0$. Similar to above where we factor $a-b$ out, we get $a+b+1=0$, or $a+b=-1$.

Now substituting this back in, we can get

$$\begin{aligned} -(a^2+b^2)+3a^2+3ab+3b^2+5=0 \\ -a^2-b^2+3a^2+3ab+3b^2+5=0 \\ 2a^2+2b^2+3ab+5=0 \end{aligned}$$

Now using the above where $a+b=-1$, we can notice that we can actually find a way to write similar to the terms of the other equation we got. Multiplying both sides by 2 and squaring, we can get $2(a+b)^2=2$. This is equal to $2=2a^2+2b^2+4ab$. So substituting some values in, we can get

$$2-ab=2a^2+2b^2+3ab+5$$

. So we can rewrite this now as

$$2-ab-(2a^2+2b^2+ab)$$

Note that term in parenthesis is just equal to -5, so we get $2 - ab + 5 = 0$, therefore $ab = 7$.

Now we can find A by just using the equations given originally.

Adding both $a^2 + a$ and $b^2 + b$, we get $a^2 + b^2 + a + b = 2A$.

$a^2 + b^2$ is equal to $(a+b)^2 - 2ab$, or $1 - 14 = -13$.

Therefore, we get $-13 - 1 = -14 = 2A$, or $A = \boxed{-7}$.

2004 HMMT Algebra/4

November 21, 2024

Find all real solutions to $x^4 + (2-x)^4 = 34$.

Solution:

Note that $2-x$ and x are symmetric around 1, so substituting $x = t+1$, we can get $x = t+1$ and $2-x = 1-t$.

We can write $(1+t)^4 + (1-t)^4 = 34$ as a result of this.

Expanding, the two we get

$$\begin{aligned} (1+2t+t^2)^2 + (1-2t+t^2)^2 \\ (1+2t+t^2+2t+4t^2+2t^3+t^2+2t^3+4) + (1-2t+t^2-2t+4t^2-2t^3+t^2-2t^3+t^4) \\ 2t^4 + 12t^2 = 32 \\ 2t^4 + 12t^2 - 32 = 0 \end{aligned}$$

Dividing by 2, we get $t^4 + 6t^2 - 16 = 0$.

Substituting $t^2 = a$, we can rewrite this as $a^2 + 6a - 16 = 0$.

Factoring results in $a = -8$ and $a = 2$. Since t^2 cannot be equal to -8, the only number for a that works is 2. Therefore, $t = \pm\sqrt{2}$.

Substituting this back to the original substitution of $x = t+1$, we get the answer as $\boxed{1 \pm \sqrt{2}}$.
